ABSTRACT

CD4 T cells survey and maintain immune homeostasis in the brain, yet their differentiation states and functional capabilities remain unclear. Our approach, combining single-cell transcriptomic analysis, ATAC-seq, spatial transcriptomics, and flow cytometry, revealed a distinct subset of CCR7+ CD4 T cells resembling lymph node central memory (T_{CM}) cells. We observed chromatin accessibility at the *CCR7, CD28, and BCL-6* loci, defining molecular features of T_{CM}. Brain CCR7+ CD4 T cells exhibited recall proliferation and interleukin-2 production ex vivo, showcasing their functional competence. We identified the skull bone marrow as a local niche for these cells alongside CNS border tissues. Sequestering T_{CM} cells in lymph nodes using FTY720 led to reduced CCR7+ CD4 T cell frequencies in the cerebrospinal fluid, accompanied by increased monocyte levels and soluble markers indicating immune activation. In macaques chronically infected with SIVCL757 and experiencing viral rebound due to cessation of antiretroviral therapy, a decrease in brain CCR7+ CD4 T cells was observed, along with increased microglial activation and initiation of neurodegenerative pathways. Our findings highlight a role for CCR7+ CD4 T cells in CNS immune surveillance and their decline during chronic SIV highlights their responsiveness to neuroinflammation.

INTRODUCTION

Antigen-experienced T lymphocyte subsets, encompassing central (T_{CM}), effector (T_{EM}), and tissue resident memory T cells (T_{RM}), actively survey and inhabit major organ systems, contributing to immune defense and tissue function (1). Lymphocyte surveillance of the central nervous system (CNS) primarily takes place at two barriers: the blood-cerebrospinal fluid barrier (BCSFB) and the blood-brain barrier (BBB). The CSF serves as a key site for T lymphocyte ingress into the CNS during homeostasis, functioning as an immunological equivalent of lymph (2). CSF CD4 T cells express markers such as CCR7, CD27, and CD45RO, characteristic of T_{CM} (3, 4). Beyond the CSF, recently, CD8 T_{RM} expressing CD69 and CD103 have been identified in human brain (5). While T cells reside in CNS niches during homeostasis, our understanding of specific CD4 T cell subsets in the CNS and its border tissues remains incomplete. Bridging this gap is important to understand underpinnings of immune dysregulation during neuroinflammation. This is particularly relevant in HIV infection, where CD4 T cells are primary targets, and chronic neuroinflammation persists in HIV-infected patients despite virological suppression (6).

We utilized a non-human primate model, the rhesus macaque, to study memory CD4 T cell subsets in the CNS. The rhesus macaque is particularly suited for CNS immunology research due to its close similarity to humans, including genetic diversity, a specialized neocortex, and complex meningeal structures (extensive dural and leptomeningeal layers). These features, along with a comprehensive spectrum of memory T cell differentiation states, make it an excellent model for exploring CNS T lymphocyte function. Additionally, perfusing the macaque brain enables precise identification of local brain immune populations while minimizing vascular contamination.

Diverging from the conventional distribution patterns of memory T cells in non-lymphoid tissues, we report that distinct CD69 and CCR7 CD4 T cell subsets populate the macaque brain parenchyma. CNS CCR7+ CD4 T cells exhibit phenotypic and functional features of T_{CM} including

4

96   production of interleukin 2 and the capacity for rapid recall proliferation. Furthermore, CCR7+ CD4

97   T cells reside in the skull bone marrow. Our findings show decreased frequencies of this subset

98   during SIV-induced chronic neuroinflammation, emphasizing responsiveness of CCR7+ CD4 T

99   cells to CNS disruptions.

RESULTS

Single-cell transcriptomic analysis of CD45+ leukocytes identifies core T cell gene signatures in rhesus brain. We previously identified T cell transcripts within synapse-dense brain regions through RNA sequencing (7). However, paucity of T cells amidst a predominance of neuronal and glial transcripts limited our assessment of T cell heterogeneity. To bridge this gap, we applied single-cell(sc) transcriptomics on cryopreserved CD45+ cells to elucidate transcriptional networks underlying memory T cell states in the non-inflamed brain parenchyma. T cells, distinguishable by flow cytometry, constituted an average of 20% of CD45+ cells with a CD4:CD8 ratio of 0.2:1 (**Figure S1**). Sc-RNA sequencing (seq) was performed on viably frozen CD45+ cells isolated from healthy macaque brain and spleen (**Figure 1A**). We enriched CD45+ cells for sequencing by positive selection and sorting for purity and viability (**Figures 1B-C**). A median of 4,952 and 3,151 CD45+ cells from the brain and spleen, respectively were sequenced, resulting in 19,000 single-cell transcriptomes passing quality control (**Figures S2A-E**). Marker gene analysis validated our approach, demonstrating high CD45 (*PTPRC*) expression (**Figure S2F**).

Transcriptome comparisons across tissues showed unique enrichment profiles. The spleen had a more pronounced B cell signature than the brain (**Figure 1D**), particularly in immunoglobulin-related genes (*ENSMMUG00000015202* [human orthologs IGHG1-4], *ENSMMUG00000002764* [human orthologs IGHA1 and IGHA2], *IGHM*, *IGKC*) and genes regulating B cell functions (*EBF1*, *BACH2*, *RelB*), antigen presentation (*CD74*, *HLADMB*, *HLADRA*), and signaling (*ALCAM*, *CD83*, *TRAF3*)(8). In contrast, CD45+ cells in the brain showed enriched T cell gene signatures. This included the T cell receptor α constant gene (*TRAC*), TCR signaling regulators (*TAOK3*, *Sos1*) (9), T cell metabolism-associated genes (*ERN1* and *TXNIP*)(10), and genes regulating effector and T_CM programs (*HSP70*, *DNAJB1*, *HSPH1*, *GZMA*, *ID2*, HELIOS (encoded by *IKZF2*), and *IL-*

147   *7R* (11). We verified predominance of B cells in spleen and T cells in brain through marker gene

148   analysis and cell type cluster annotation (**Figures S2G-H**).

149

150   **Non-inflamed brain harbors both effector memory (T_{EM}) and resident memory (T_{RM}) CD8 T**

151   **cells.**

152   We next pursued high-resolution unsupervised clustering with automated label transfer using

153   blueprint_encode (12, 13). Ten cell clusters were identified, with manual inspection and marker

154   gene analysis (14) confirming six as T cells (**Figures 1E, S3A**). These T cell clusters were isolated

155   and independently reclustered, identifying three shared T cell subtypes between brain and spleen:

156   Terminal effector memory CD8 T cells (T_{EM} 8 cluster; C0, C2, C3, C5), T_{CM} CD8 T cells (T_{CM} 8

157   cluster; C1, C4, C6) and T_{CM} CD4 cells (T_{CM} 4 cluster; C7 and C8) (**Figures 1F, S3B**).

158

159   The T_{EM}8 clusters (C0, C2, C3, C5) displayed varied gene expression (**Figures 2A, S3C-D**)

160   highlighting functional diversity in brain CD8 T_{EM} cells. C0 showed genes typical of *effector*

161   *memory* cells, such as S100 calcium- binding proteins (*S10010*, *S100A4*), *SH3BGRL3* expressed

162   by T_{h}1 cells, regulatory receptor *CD52*, molecules driving T cell activation (*FLNA* and the scaffold

163   protein *AHNAK*, cytolytic molecule *GZMB*, and transcription factors (TF) *KLF2* and *KLF3*. C2 was

164   rich in *cytotoxic molecules* like *GZMA*, *GZMK*, *GZMB*, *GNLY*, *KLRC3*, *HELIOS*, and *HOPX* akin

165   to human KIR+ CD8+ T cells (15). In contrast, C3 was enriched for DNAJ/Heatshock genes

166   regulating memory T cell quiescence, Ikaros (encoded by *IKZF1*) and *TXNIP*, which suppress

167   proliferation and inflammatory cytokines in T cells (16). C5 was characterized by genes linked to

168   cell cycle progression and survival (*AKAP13*, *BABAM2*, *INPP4A*). Elevated expression of effector

169   (*GZMA*, *KLRC2-3*, *CCL5*, *IFNG*), residency, and longevity genes (*ID2*, *AHR*, *IKZF2*, *HOPX*, *CD69*,

170   *BCL2*) in the brain versus spleen (**Bar graph in 2A**) suggested that brain CD8 T_{EM} cell clusters

171   encompassed resident and effector memory subsets, aligning with observations in mouse and

172   human studies (5, 17).

Single-cell transcriptomic analysis reveals central memory CD4 and CD8 (T$_{CM}$) subsets in brain. We shifted our focus to the remaining CD8 T cell clusters (C1, C4, C6) annotated as T$_{CM}$. There were notable gene expression differences between brain and spleen (**Figures 2B, S3E**). with brain C1 showing higher expression of memory-related genes (*IL-7R, JUN, FOSB, THEMIS*), along with anti-inflammatory regulators (*ATF3, ZFP36L2, NR4A2*). In addition, C1 expressed genes regulating mitochondrial function and memory cell maintenance (GLUT3, BTG1). C4 cells exhibited elevated levels of cytotoxicity and residency markers (*GAMM, GZMK, CRTAM*), and *NFκB*, with reduced *IL-7R* expression. Brain C4 also showed TCR activation markers (S*LC2A3, NR4A2)*, suggesting potential reactivation. C6 was distinguished by an abundance of *TNFAIP3*, which inhibits IFNγ and TNFα in CD8 T cells. These signatures of brain CD8 T$_{CM}$ clusters indicate specialized roles in memory, effector, and regulatory functions.

Two CD4 T$_{CM}$ clusters, C7 and C8 were discerned among CD4 T cells. C7 was characterized by abundance of co-stimulatory molecules (*CD28* and *ICOS*), *IL-7R* and survival-related TF, *BACH2*, quiescence-associated *FOXP1*, negative regulator of T cell activation, *PELI1*, memory-associated genes (*LTB*, *MAF*, *NFATC1*), and integrin *ITGβ1* (**Figures 2C, S3F**). C8, shared memory gene expression with C7 (*IL-7R*, *BACH2*, *LTB*), and expressed T$_h$17-associated genes (*CCR6*, *AHR*, *RORA*). Gene set enrichment analysis showed alignment with longevity and MAPK pathways, and downregulation of effector pathways such as NFκB, RIG-I and TNF signaling (**Figure 2D-E**). Overall, scRNA-seq analysis of CD45+ cells revealed a spectrum of T cell states in the brain and spleen.

T$_{CM}$/T$_{RM}$ loci accessible in T cells within the brain. To explore mechanisms regulating T$_{CM}$ and T$_{RM}$ differentiation and validate our scRNA-seq data, we profiled the transcriptome and epigenome in parallel. We isolated nuclei from CD45+ and CD45- cells extracted from brain (**Figure 3A**) and generated over 1.5 billion reads across 47,000 nuclei, with an average of 1378

199 genes/nuclei (**Figures S4A-D**). Transcriptome classification revealed distinct cell clusters,

200 including glial cells (microglia, oligodendrocytes), neurons, endothelial cells, cancer cells, and T

201 cells (**Figures 3B, S4E-F**). The largest immune cluster comprised of macrophages, microglia,

202 and T cells, with each cluster expressing genes encoding proteins with known cell-type

203 distinctions. Specifically, cells in the macrophage cluster expressed *CD86*, *TSPAN14*, and

204 *TNFRSF21*. The microglia cluster expressed *ST6GALNAC3*, *ENTPD1*, and *P2RY12*, while T cell

205 clusters expressed the T_h1 transcription factor [*STAT4*], T cell adaptor protein [*SKAP1*], as well

206 as kinases and signaling molecules [*TNIK*, *ITK*, *FYN*]) (**Figures 3C, S4F**).

207

208 We identified expression of several key genes regulating T cell differentiation and function,

209 including zinc finger TF (*ThPOK* and *GATA3*), Runx TF (*RUNX1* and *RUNX3*), T-box TF (*EOMES*

210 and *TBX21*), inhibitor of DNA binding proteins (*ID2* and *ID3*), TF regulating cytokine production

211 (*AHR* and *STAT4*), markers of antigen-experienced cells (*CD44*, *IFNG*, *ITGα4*, and *ITGβ1*),

212 markers of T cell residency (*PRDM1*, *ITGα1*, *ITGαE*, *CD69*, *GZMB*, *KLRG1*, and *PRF1*), and

213 markers of long-lived cells with T_{CM} features (*BCL2* and *BCL6*) (**Figure 3D**).

214

215 To quantitatively evaluate genes enriched in T cells, we conducted differential gene expression

216 (DGE) analysis across T cell and microglial clusters. Within microglia, we discovered enrichment

217 of canonical brain resident microglia transcripts, including *CX3CR1*, *ITGαM*, *TMEM*, and *SIGLEC*

218 (18-20) (**Figure 3E**). In contrast, genes highly expressed by the T cell cluster included those

219 regulating T cell signaling (*TRAC*, *ITK*, *THEMIS*, *TNIK*), TF controlling CD4 and CD8 T cell

220 programs (*STAT4*, *RUNX3*), T cell migration (*CD44*, *ITGα4*), residency (*CD69*), and T cell survival

221 (*BCLA11B*, *BCL2*), including the TF *ETS-1*, which regulates IL-7R expression (21) (**Figures 3E,**

222 **S4G**). Genes involved in T_h17 function, *RORα* and *AHR* were also expressed in keeping with the

223 transcriptome of $T_{CM}4$ C8. Furthermore, a similar T cell gene expression profile was observed

224 when comparing macrophages to T cells, with the IL-12-induced CD4 T_h1 TF, *STAT4* being the

225 most highly expressed gene in T cells (**Figure S4H**). ATAC-seq analysis highlighted open

226 chromatin in regulatory regions of STAT4, especially within the T cell cluster, aligning with high

227 STAT4 expression (**Figure S4I**). Additionally, downstream targets of *STAT4*, including *IFNγ* and

228 *ICOS*, were distinctively expressed in T cells, differing from patterns in innate immune cells

229 (**Figure S4J**). These genes also featured as top markers in the T cell cluster in our sc RNA

230 sequencing of CD45+ cells.

231

232 To formally ascertain whether T cell clusters expressed genes overlapping with our scRNA seq

233 profiles, we examined 7798 transcripts from snRNA seq-derived immune clusters. We then used

234 DGE p values for each expressed gene in T cells relative to macrophages and microglia. For

235 comparison, we also included DGE p values of microglial transcripts relative to macrophages.

236 Gene set enrichment analysis showed overlap with top 20 marker genes expressed by scRNA

237 seq T cell clusters, including classical effector/memory transcripts such as *GZMB*, *CRTAM*, and

238 *IL-7R*, among others (**Figure 3F**). Additionally, when aligning these DGE genes with known T cell

239 signatures from mouse studies, we found that ITGαE (integrin receptor for T_{RM}) and TCF7 (TF

240 critical for T_{CM} development) were notably present in T cells over macrophages/microglia

241 (adjusted p value < 0.05).

242

243 To assess T_{CM} gene accessibility, we focussed on genes vital for T_{CM} function and survival - *CD28,*

244 *IL-7R*, *and BCL2* - which macrophages and microglia also expressed. T cells exhibited increased

245 ATAC peaks for *CD28* and *IL-7R*, suggesting an open chromatin configuration, especially in their

246 promoter regions (**Figure 3G**), whereas *BCL2* accessibility was similar across immune cells

247 (**Figure S4K**). Despite low expression, *CCR7* chromatin accessibility was higher in T cells,

248 contrasting with CCR7 absence in innate immune cells. Additionally, our analysis of gene

249 expression patterns and motif enrichment, using the HOMER database, revealed that TFs from

250   the bZIP, RUNT, and ATF families, pivotal in regulating T_{CM} genes, were significantly enriched,

251   marking about 30% of target sequences in T cells.

252

253   To pinpoint genes controlling memory T cells states, we re-clustered 2,158 T cells, which revealed

254   four distinct clusters (**Figure 3H**). Since CCR7 was expressed in < 1% of cells across all clusters,

255   we probed the promoter accessibility within T_{RM} genes across three major T cell clusters (C0-C2).

256   With *CD69* and *GZMB* marking T_{RMs} and their expression in C1, we anticipated and confirmed

257   ATAC peaks for key T_{RM} genes in C1. Indeed, peak tracks showed increased chromatin

258   accessibility for regulatory regions of *CD69, GZMB, and ITGαE* in C1 (**Figure 3I**). The sequencing

259   outcomes indicate that the primate brain harbors T cells with diverse chromatin accessibility

260   landscapes for genes that govern residency and migration, suggesting the presence of T cells

261   with potential resident and central memory features.

262

263   **CCR7$^+$ CD4 T cells in CNS share phenotypic features with T_{CM} in blood and lymph nodes.**

264   To validate and extend our sequencing observations, we investigated the immune makeup of the

265   CSF. CSF samples were collected from the foramen magnum, alongside paired axillary lymph

266   node aspirates and blood samples (**Figure S5A**). Unlike blood, CSF exhibited minimal B cell and

267   monocyte presence and a preferential infiltration of T cells at steady state.

268

269   CSF T cells showed predominance of CD28^{high} CD4 memory T cells, with an absence of terminally

270   differentiated (CD28- CD95+) and naive (CD28^{int} CD95-) subsets, consistent with human

271   phenotypes (22). Relative to CD28^{high} subset in blood, approximately 50% of CSF CD28^{high} CD4

272   T cells expressed CCR7, compared to 20% in CD28^{high} CD8 T cells (**Figure S5B-C**).

273

274   We compared phenotype of CSF-derived T cells to those in matched CNS tissues and adjacent

275   lymph nodes, spleen, and blood. Brain T cells showed distinct differentiation states: CD4 T cells

276   were enriched for CD28, while CD8 T cells were mostly CD28- (**Figure 4A**). Like in the CSF,

277   CD28^{high} CD4 T cells in the parenchyma showed varied CCR7 expression (**Figures 4B**). We

278   assessed CCR7+ CD4 T cells in the CNS (choroid plexus and brain parenchyma) to those in

279   corresponding lymphoid compartments (deep cervical lymph nodes and spleen) to identify

280   similarities to T$_{CM}$. Analysis of receptor expression revealed lower per cell CCR7 expression in

281   the CNS than in lymphoid tissues. (**Figure 4C**).

282

283   CCR7+ CD4 T cells in each tissue were less likely to express CD69, a key T$_{RM}$ marker (**Figure**

284   **4D**). PD-1 levels, indicative of TCR stimulation, were similar across subsets, aligning with findings

285   in CD8 T$_{RM}$ (23) (**Figure 4E**). Given known CCR5 expression in intestinal CD69^{+} CD4 T$_{RM}$ (24),

286   we explored CCR7- CD4 T cells for increased CCR5 alongside higher CD69 levels. This pattern

287   was confirmed in the CNS, but not in lymphoid tissues (**Figure 4F**). Thus, CD4 T cells within the

288   non-inflamed brain parenchyma mainly show CD28^{high} expression, bifurcating into subsets based

289   on CD69 and CCR7, with CCR7+ T cells resembling their lymphoid counterparts.

290

291   We performed FLOW SOM clustering on CSF CD4+ T cells (n=4) to determine if CCR7+ and

292   CCR7- subsets represent distinct clusters. Based on expression of specific T$_h$1 (CXCR3, CCR5),

293   T$_h$17 (CCR6), activation and memory markers (CD95, PD-1, CD69), 5 metaclusters were defined

294   with varying levels of CCR7 expression (**Figure S6A**). CCR7- and CCR7+ clusters showed

295   enrichment of distinct surface markers; CCR5 and PD-1 were enriched in the CCR7- cluster, while

296   CCR6 was enriched in the CCR7+ cluster (**Figure S6B**).

297

298   We then examined if CCR7+ CD4 T cells in the CSF resembled quiescent T$_{CM}$, and conversely,

299   whether CCR7- CD4 T cells exhibited T$_{RM}$ or activated effector memory cell features. Unlike blood

300   CCR7- CD4 T cells in CSF predominantly expressed CD69, reflecting patterns in the brain (**Figure**

301   **4G, S7**). CSF CCR7- subset also showed higher expression of CCR5 and CXCR3, as well as

302   activation markers like ICOS, EOMES, PD-1, and HLA-DR. Both subsets expressed CD127 and

303   BCL-2. In summary, CCR7+ CD4 T cells in the CSF and brain display core T_{CM} traits, like those

304   in lymphoid tissues. We postulated that these CNS CD4 T cells would exhibit functional hallmarks

305   of T_{CM} by producing IL-2. Upon PMA/Ionomycin stimulation, CSF CD4 T cells indeed

306   demonstrated polyfunctionality, including IL-2 production (**Figure 4H**).

307

308   **Sequestration of CD4 T_{CM} in lymphoid tissues reduces CCR7+ CD4 T cell frequencies in**

309   **CSF and increases soluble inflammatory markers**. To determine if CNS CCR7+ CD4 T cells

310   displayed migration patterns to and from lymphoid tissue, a hallmark of T_{CM}, we explored the effect

311   of FTY720, known to trap T_{CM} cells in lymph nodes, on T_{CM} frequencies in the CSF. We treated

312   twelve rhesus macaques with FTY720 (30 µg/kg/day) for a month (**Figure 5A**) and analyzed

313   paired blood and CSF T cells over eight weeks, tracking T cells within the subarachnoid space

314   (SAS) through FTY720-induced lymphocyte depletion and the subsequent rebound post-

315   treatment.

316

317   Analysis of blood T cells showed rapid decline in total CD4 T cells one week after FTY720, while

318   CD4 T cell counts significantly decreased in CSF at week 4 post FTY720 (**Figure 5B**). Consistent

319   with FTY720 mediated inhibition of S1PR-mediated T cell egress and retention of CCR7-

320   expressing T cells in lymph nodes as documented in macaques (25), rapid sequestration of naive

321   T cells, the subset exhibiting the highest per cell expression of CCR7 ensued. This was evidenced

322   by a notable 4-fold reduction in the absolute counts of naive (CD28+ CD95-) T cells within week

323   1 of FTY720.

324

325   By week 4, there was an additional reduction in naive T cells, marked by a 100-fold decrease in

326   CD4 T cells and an 80-fold decline in CD8 T cells compared to baseline (**Figure S8A**). The

327   heightened CD4 T cell decline can be attributed to their shorter lymph node residency time,

328 rendering them more susceptible to mechanisms impeding their egress (26). It took up to two

329 weeks for a significant decrease in the peripheral CD4 T_{CM} pool to manifest, culminating in a 17-

330 fold reduction by week 4. This decline was accompanied by a significant decrease in CSF CCR7+

331 CD4 T cells by week 4 indicating recruitment of CCR7+ CD4 T cells into the SAS from lymphoid

332 tissues via the systemic compartment.

333

334 While blood CD8 T_{CM} frequencies fell (**Figure S8B**), CSF CD8 T cells remained stable, potentially

335 due to CD28-CD95+ CD8 T cells in the CSF, which are mostly CCR7- and less affected by

336 FTY720. This could also reflect their migration from non-lymphoid tissues. Consequently, the CSF

337 CD4:CD8 ratio significantly dropped by week 4. The blood showed an increased frequency of

338 CD28- T_{EM} early on, with CD4 and CD8 T cells CM:EM ratios shifting at weeks 1 and 4, consistent

339 with the expected impact of CCR7- EM cells not being retained in lymph nodes. However, the

340 CSF T cell CM:EM ratio remained unchanged throughout the four weeks, indicating a tight

341 regulation that limits CD28- CD95+ CD4 T cells from entering the SAS (**Figure 5B**). Cytokine

342 analysis showed a transient decrease in T_h1, T_h17, and regulatory cytokines in plasma after

343 treatment, demonstrating extensive effects on CD4 helper subsets, although these cytokines were

344 undetectable in the CSF (**Figure S8C**).

345

346 In mice, T cell depletion from meninges induces pro-inflammatory innate immune skewing (27).

347 We therefore examined monocyte frequencies post FTY720 to gauge compensatory increase in

348 the SAS. The data showed a net increase in monocytes in the CSF at week 4, significantly

349 increasing monocyte/CD4 T cell ratio (**Figure 5C**). Significant elevation of CSF, but not blood,

350 monocyte chemotactic protein-1 (MCP-1) at week 4 implied CSF monocyte influx was chemokine

351 mediated. Moreover, CSF CCR5+ CD4 T cells significantly increased, and there was an inverse

352 association (r = -0.73; p< 0.01) between CCR7+ and CCR5+ CD4 T cells (**Figure S8D**). In

353 conclusion, the data suggest that CSF CCR7+ CD69- CD4 T cells are mainly recruited from

354   lymphoid tissues. Moreover, immune activation linked to reduced CCR7+ CD4 T cells in the SAS

355   suggests a role for these cells in neuroimmune homeostasis.

356

357   **CCR7$^+$ CD4 T cells in CNS exhibit functional T$_{CM}$ features and reside within skull bone**

358   **marrow.** Recognizing the importance of bone marrow (BM), particularly within the skull (28, 29),

359   for T$_{CM}$ localization we explored presence of CD4 T cells with T$_{CM}$ attributes in this niche. After

360   manually extracting BM cells from the skull, single-cell suspensions were stained to identify innate

361   and adaptive immune cells. Like mouse brain findings, our analysis identified three immune

362   subsets among CD3- CD45+ cells based on CD11b and HLA-DR expression (**Figure S9**). T cells

363   comprised 71% of the CD45+ population in skull BM, echoing CSF T cell prevalence (**Figure 6A**),

364   with a CD8 to CD4 T cell ratio mirroring that in brain tissue (**Figure 6B**). Like in the CNS, CCR7

365   expression in CD28+ CD4 T cells was variable, while CD28- CD4 T cells largely lacked CCR7

366   (**Figures 6C-D, S10**).

367

368   Phenotypic analysis revealed distinct profiles between CNS CD4 T cell subsets: CCR7+ cells

369   showed higher integrin α4 and elevated CCR6, but lower CCR5 and CXCR3 expression

370   compared to CD69+ cells, which had more pronounced PD-1 expression, in both skull BM and

371   brain (**Figure 6E**). Functional characterization of memory CCR7- and CCR7+ CD4 subsets

372   demonstrated that both brain CCR7- and CCR7+ CD4 T cells mounted recall proliferation ex vivo,

373   while splenic CCR7+ CD4 T cells, and to a lesser extent CCR7- CD4 T cells were Ki67+ (**Figure**

374   **6F**). Analysis of cytokine production following PMA/I stimulation showed that CNS CCR7+ CD4 T

375   cells produced a higher relative IL-2, while the CCR7- subset produced high levels of IL-2, IFNγ,

376   and TNFα. This cytokine expression pattern was consistent with T$_{CM}$ functionality, as exemplified

377   by a similar cytokine pattern in splenic CD4 T$_{CM}$ (**Figure 6G-I**). In summary, the data highlight the

378   presence of a CCR7+ CD4 population in the brain and skull BM exhibiting T$_{CM}$-like characteristics,

379   akin to T$_{CM}$ in the spleen.

vRNA within frontal and temporal lobes during chronic SIV infection. To better understand

CD4 T_{CM} in the CNS, we investigated these cells in a model of chronic viral neuroinflammation

(30). Aged rhesus macaques (17-20 years) were infected with neuropathogenic SIVCL757 to elicit

chronic neuroinflammation and establish CNS virus presence. After the post-acute phase, to

ensure CNS viral dissemination, suboptimal antiretroviral therapy (ART) was initiated during

weeks 16 to 52 post-SIV when CSF and plasma viral RNA (vRNA) levels exceeded the threshold

of detection (> 15 vRNA copies/ml). This treatment was interrupted when vRNA levels fell below

the threshold of detection (**Figure 7A**). We adopted this regimen to induce cycles of viral

suppression and rebound within the CNS, simulating scenarios in individuals at risk for

neurological co-morbidities due to chronic neuroinflammation (6). An exception to this protocol

was followed in the case of 33191, which did not receive ART. This decision was made because

CSF vRNA levels exceeded 15 copies/ml only at a single time point during week 6 and

subsequently dropped below the threshold of detection. Longitudinal collections of CSF and

matched blood from infected animals were conducted for up to 116 weeks, except for one SIV+

animal (34974) that was euthanized at 52 weeks due to health complications. Prior to necropsy,

ART was interrupted in all animals (except ART-naive 33191) to induce viral rebound. At necropsy,

CNS and peripheral lymphoid tissues were collected for analysis. Age-matched control group of

SIV-unexposed animals (n=5) was also assessed.

Following infection, viremic animals (n=4) exhibited median plasma viral loads of 165,000

copies/mL at week 3, with CSF viral RNA (vRNA) reaching a median of 19,750 vRNA copies/mL

(**Figure S11**). Plasma and CSF vRNA exhibited a lower magnitude and variable pattern when

compared to viral loads observed following SIVmac251 (31). Like SIVmac251, there was plasma-

CSF concordance during acute SIVCL757 infection before ART initiation. An exception was

observed in one TRIM5α-restrictive animal (32967), which displayed transient plasma viral

discordance up to week 6 post-infection. Of note, 2 animals (33191 and 34996) demonstrated

16

406   sporadic and minimal vRNA in CSF, despite plasma vRNA after the acute phase. ART initiation

407   between sixteen to forty-six weeks post-infection led to viral suppression (vRNA copies <15) in

408   plasma as early as 4 weeks and as late as 6 weeks post ART initiation. Throughout chronic

409   infection, viral loads in CSF were consistently 3 log-fold lower than those in plasma (median viral

410   loads/ml at week 108: plasma, 50,000; CSF, 65), aligning with our findings in acute

411   SHIV.C.CH505 (**Figure 7B**) [25].

412

413   At necropsy, 3mm post-mortem punch biopsies were collected to assess vRNA and vDNA in

414   various brain regions, border tissues, CNS-draining lymph nodes, and peripheral lymphoid tissues

415   (**Figure 7C**). The frontal lobe, linked to cognition, displayed vRNA positivity in both gray and white

416   matter across all animals tested. However, vDNA was undetectable. The detection of vRNA and

417   vDNA exhibited variability in the temporal lobe, limbic system, and other brain and border tissues.

418   While the CNS-draining lymph nodes and peripheral lymphoid tissues showed vRNA in all animals,

419   vDNA was not consistently detected across CNS tissues in certain animals. The presence of

420   widespread vRNA within the CNS coupled with low levels of vDNA, may be attributed to ineffective

421   viral integration of SIVCL757 within CNS myeloid and CD4 T cells.

422

423   CSF lymphocyte analysis showed trend for CD4 T cell reduction during the first 12 weeks of

424   infection (not significant), while CD8 T cells exhibited an increase (p<0.05; fold change: 13). Both

425   CD4 and CD8 T cell frequencies stabilized during the chronic phase (**Figure 7D**). These findings

426   highlight widespread vRNA in the CNS, low vDNA levels, and acute changes in CD4 and CD8 T

427   lymphocyte populations within the CSF following SIVCL757 infection.

428

429   **Spatial profiling of hippocampus shows induction of neuroinflammatory and**

430   **neurodegenerative gene programs during chronic SIV infection.** To assess the extent of

431   neuroinflammatory responses during chronic SIV infection, we utilized two complementary

432   methods: spatial transcriptomics on the hippocampus and single-cell analysis of CD45-enriched

433   cells derived from brain parenchyma. Initially, we examined T cell distribution in the human brain

434   by performing immunohistochemistry (IHC) analysis on hippocampal sections from both

435   glioblastoma patients (GBM-01) and non-demented individuals from the Netherlands Brain Bank.

436   We aimed to identify neurons (NeuN), myeloid cells (CD11b, IBA1), and lymphocytes (CD45, CD3,

437   CD4). Healthy tonsil sections showed abundant T cells and myeloid cells and lacked neuron-

438   specific staining. In contrast, hippocampal sections from non-demented patients displayed

439   microglia, neurons, T cells, and monocytes, primarily around blood vessels (**Figure S12**).

440   Glioblastoma patient-derived hippocampal tissue exhibited a pronounced distribution of T cells

441   throughout the brain parenchyma.

442

443   With the presence of T cells in the human brain established by IHC, we analyzed hippocampal

444   tissue from chronically SIV-infected macaques (one healthy control, 33980, and one SIV+ animal,

445   35595) using the Nanostring Digital Spatial Profiler (DSP) platform. Using CD3, CD45, and NeuN

446   as morphological markers to identify T cells, leukocytes, and neurons, we selected 24 regions of

447   interest (ROIs) with varying CD45 expression levels, covering distinct spatial zones within the

448   hippocampus. These zones included areas around CA1, small and large blood vessels, and

449   parenchymal regions (**Figure 8A**). The expression of CD45, CD3, and NeuN proteins showed

450   heterogeneity across the selected 24 ROIs. Using the fluorescence signal of CD3 and CD45, we

451   identified T cells primarily within blood vessels. Subsequently, these 24 ROIs underwent

452   comprehensive 147-plex antibody profiling and whole transcriptomic analysis (WTA). The data

453   showed higher *CD3ε* RNA counts and lower CD3ε protein counts in SIV-infected ROIs, suggestive

454   of possible CD3 protein internalization due to activation (**Figure 8B**). Antibody profiling revealed

455   the expected enrichment of signals corresponding to glial cells (oligodendrocytes [myelin basic

456   protein], astrocytes [GFAP, APOE, S100B, amyloid β, Vimentin], microglia [TMEM119, CD11b,

457   IBA1, P2RY12] neuronal proteins (synaptophysin, neurofilament light chain, Tau, NCAM [CD56],

458 Calbindin), endothelial and muscle cells [CD31, CD34, Fibronectin]. With respect to immune

459 proteins, we detected myeloid cell markers (CD14, CSF1R, CD11c, HLA-DR, CD40, CD68),

460 memory T$_{CM}$ markers (CD127, BCL-2, BCL-6), effector/resident cell marker (GZMB), and

461 transcriptional regulators (BCL-6, FOXP3) (**Figure 8C**).

462

463 **Activation of neurodegenerative and metabolic gene programs in SIV infected**

464 **hippocampus.** DGE analysis across control and SIV-infected ROIs (n =12 control; n=12 SIV)

465 demonstrated altered expression of numerous neurodegenerative and metabolic KEGG pathway

466 genes in response to SIV; specifically, 52 metabolic and 25 neurodegenerative KEGG pathways

467 were disrupted with SIV (**Figure 8D-E**). We saw decreased expression of ETC genes (*NDUFB7*,

468 *NDUFB11*, and *COX4I1*) and a decrease in inositol polyphosphate phosphatase 4A (*INPP4A*), a

469 suppressor of glutamate excitotoxicity in the CNS linked to neurodegeneration in the striatum.

470 Additionally, we identified increase in *BST1*, a risk factor for neurodegenerative diseases (ND).

471 Downregulation of *HSP5*, *CTNNB1*, *COX4I1*, *KLC1*, *DCTN1*, and *PSMB7* linked to various

472 neurodevelopmental and ND was also observed (32). The upregulation of the mitochondrial

473 calcium uniporter, located on the inner mitochondrial membrane, is noteworthy, as disturbances

474 in calcium homeostasis are linked to ND (33-37).

475

476 **Single cell analysis identifies activated inflammatory macrophage population in SIV**

477 **infected brain.**

478 As spatial transcriptomics does not offer single-cell resolution, we complemented our analysis

479 with single-cell gene expression of CD45+ enriched brain cells from control animals (33980,

480 33994), as described in Figure 2, in conjunction with SIV+ animal 32967. To delineate myeloid

481 cell activation at a deeper resolution, we subclustered the myeloid cluster (macrophages and

482 microglia) into eight distinct subclusters. Utilizing established microglial markers (*PTPRC, ITGαM,*

483 *CX3CR1, and P2RY12*), cluster 3 and cluster 5 were designated microglia-like (**Figure 8F**), while

19

484   clusters 0, 1, 2, 4, and 7 expressed definitive macrophage markers *CD68* and *FCGR1A.* HLA

485   genes *B2M* and *CD74* were primarily expressed in clusters 0, 2, 4, and 6. Genes related to anti-

486   viral responses (*IFIT2, IFIT3, IRF3, MAVS, STING1, TNF*) and chemokine trafficking (*CCL5,*

487   *CCL19, CCL21, CCR5, CXCR3*) showed variability but were generally expressed at low levels.

488   Noteworthy was cluster 4, which was enriched in SIV-brain. Cluster 4 displayed a gene signature

489   of activated inflammatory macrophages, featuring high expression of MHC genes, and *IL-1β*.

490   Assessment DGEs in total CD45+ cells showed alterations in chemokine, T cell receptor, MAPK

491   signaling pathways due to chronic SIV infection. Key genes linked to T cell function (*STAT4*,

492   *PTPN6*, *NFATC3*, *NFκB1*, *JAK3*, etc.) and MAPK signaling pathway (*EPHA2*, *PTPRR*, *TRAF2*,

493   *NFATC3*) (*SPI1*, *NFATC3 etc.*) were altered (**Figure 8G**). In summary, spatial and single-cell

494   analyses unveiled significant alterations in genes governing neuroinflammatory processes in both

495   myeloid and T cells during chronic SIV infection.

496

497   **CCR7+ CD4 T cell frequencies decreased during SIV-induced neuroinflammation.**

498   After uncovering a complex interplay of genes involved in the initiation and progression of

499   neuroinflammation in response to viral presence in the brain, we examined cellular and soluble

500   markers in the CNS. We assessed myeloid populations (microglia [CD11b+CD45lo/int],

501   macrophages, monocytes [CD45+CD14/CD16+]), and lymphoid populations (CD4 and CD8 T

502   cells) from single cell suspensions. We observed a significant increase in brain monocytes,

503   indicative of active recruitment to CNS during chronic SIV (**Figure 9A**). Correspondingly, there

504   was a significant increase in plasma levels of CCL2, a monocyte chemoattractant (data not

505   shown). We also investigated microglial activation in the brain and found that overall, HLA-DR

506   expression on microglia was not significantly different (**Figure 9B**). To explore the potential for

507   active recruitment of monocytes and/or lymphocytes to the brain, we examined a panel of

508   inflammatory analytes. Interferon protein 10 (IP-10), a chemoattractant for monocytes and T cells,

509   was significantly increased in the CSF at weeks 70-93 post-infection, suggesting ongoing

510   recruitment (**Figure 9C**). While the total CD4 T cell population in the brain remained unchanged

511   during chronic SIV (**Figure 9D**), a significant increase in the frequency of CD4 T cells expressing

512   PD-1 was noted, indicative of immune activation (**Figure 9E**).

513

514   Importantly, the CCR7+ CD69- CD4 subset was decreased in the brain during chronic SIV (**Figure**

515   **9F**), an effect not observed in adjacent CNS compartments (**Figure S13**). To determine if the

516   decrease in the CCR7+ CD4 subset was a consequence of virus mediated depletion, we

517   examined expression of chemokine receptors CXCR3 and CCR5 expressed by target cells. The

518   data showed that, on average, CD4 CD69+ cells in the CNS expressed higher relative levels of

519   CXCR3+CCR5+ arguing against virus mediated depletion of CCR7+ CD4 T cells (**Figure 9G**). In

520   sum, the data emphasize the CNS immune surveillance role of CCR7+ CD4 T cells and their

521   potential to counter neuroinflammatory processes during chronic neuroinflammation.

535

DISCUSSION

Our data show that T cells in the non-inflamed CNS exhibit diverse differentiation states, characterized by unique chromatin accessibility patterns corresponding to T_{CM} and T_{EM}/T_{RM} profiles. Beyond their presence in CSF and brain parenchyma, we also identify T_{CM} cells occupying the skull BM niche, potentially poised to replenish adjacent CNS compartments. Notably, impeding T cell egress from lymph nodes using FTY720 led to reduced CCR7+ CD4 T cells within the CSF, suggesting potential migration of T_{CM} from lymph nodes to the CSF, likely through vascular routes. Lastly, in a chronic HIV infection model, we observed a specific decline in CCR7+ CD4 T cells in the brain parenchyma.

While the presence of CCR7+ CD4 T cells in the brain challenges established paradigms of memory T cell distribution in non-lymphoid tissues, there is precedence for our observations. For instance, 90% of CSF T cells express CCR7 (4, 38), and CCR7+ T cells populate non-lymphoid tissues including the skin, gut, colon, and cervix (39-41). Moreover, ligands for CCR7, namely CCL19 and CCL21, are present in human CNS (42-44). In rodent models, CCL19 and CCL21 production in the CNS is linked to CCR7+ CD8 T cell recruitment (45). The reduction in CCR7+ CD4 T cells during chronic SIV infection could stem from multiple mechanisms: (a) CCR7 binding with CCL19 triggering its internalization, (b) Diminished CCR7 expression might result from the influx of SIV-specific CCR7- effector cells or the effector differentiation of herpes-virus specific CD4 memory cells in the brain parenchyma (38, 46-48) Notably, within the SAS, activated CCR7- T cells enter the brain parenchyma, while quiescent CCR7+ T cells migrate out of the CNS (49). (c) CCR7+ cells might migrate to lymph nodes through nasal lymphatics (50), and (d) The HIV-1 viral protein U (Vpu) could downregulate CCR7, though this assumes widespread productive infection and likely does not fully account for the observed changes (51). Conclusively establishing the relative contributions of these factors holds significant implications for neuroinflammation.

562 Currently, it remains unclear whether increased neuroinflammation is a cause or results from the

563 loss of CCR7+ CD4 T cells in the brain, or if these cells are direct targets of the virus. Thus,

564 several key questions need to be addressed to establish the underlying mechanisms, and

565 pathological outcomes of this reduction. Firstly, the co-localization of virus with CD4 T cells, as

566 observed in the brain parenchyma with SIV mac251 (31, 52), still needs confirmation with

567 SIVCL757. Secondly, increased PD-1+ CD4 T cell frequencies in the chronic SIV-infected brain

568 align with observed immune activation indices. However, there is a need for a more in-depth

569 exploration of associated pathways of immune dysregulation, such as T_h17/Treg imbalance and

570 their potential pathogenic consequences (53).This is particularly relevant as CCR7+ CD4 T cells

571 exhibit features of T_h17 and T regulatory cells. Finally, our FTY720 studies suggest broad immune

572 activation, raising questions about effects on CD4 helper subsets like T regulatory cells (54), and

573 connection to CNS immune activation.

574

575 In summary, we demonstrate that CD4 T cells with T_{CM} features reside within the primate CNS.

576 Taken together, these data support a model of CNS immunosurveillance by CCR7+ T_{CM}-like

577 population. During chronic viral infection, T_{CM}-like cell frequencies are perturbed likely due to

578 egress to the draining deep cervical lymph node or differentiation to T_{EM} in response to local

579 antigen. Further studies defining their migration potential and functional features will advance our

580 understanding of neuroimmune surveillance during homeostasis and dysregulation in disease.

581

582

583

584

585

586

587

MATERIALS AND METHODS

Sex as a biological variable. Animals of both sexes were included in the study, except for the chronic SIV study, which consisted only of females. This decision was made because females are at a higher risk for neurodegenerative diseases, and we aimed to reduce variability in our infection studies.

Rhesus Macaques. Colony bred Rhesus Macaques (*Macaca Mulatta*) were sourced and housed at the California National Primate Research Center (CNPRC) and maintained in accordance with American Association for Accreditation for Laboratory Animal Care (AAALAC) and Animal Welfare Act guidelines. All procedures were approved by the Institutional Animal Care and Use Committee (IACUC) at UC Davis. Animals (total n=47) consisted of both males (n=17) and females (n=30) with ages ranging from 8 months – 29 years. Select animals were utilized for FTY720 treatment studies (n=12) and SIV infection studies (n=5). Additional tissues were obtained from uninfected opportunistic medical culls for unrelated conditions (n=9; 4 males, 5 females; ages: 0.8-19.7 [years. months]) to bolster analyses with low sample sizes. Animal details are in **Table S1 and S2**.

FTY720 Treatment. Fingolimod (FTY720) was obtained from Millipore Sigma and given orally daily by mixing with animal feed. Animals (n=12, 10 males, 2 females; ages 3.5-5.6 [years. months]) received 30 µg/kg of FTY720 daily over four weeks.

SIV Infection Animals were infected with SIVsm804e-CL757 strain (SIVCL757) donated by Hirsch and colleagues (NIAID, NIH, Bethesda, MD)(30) . Viral stocks were thawed at 4C and diluted 16.7- fold in HBSS to a final volume of 0.5 mL and stored on ice prior to administration. Animals (n=6; 6 females; ages 17.6-20.8 were intravenously infected with 500 $TCID_{50}$. Animals

24

613   were treated with ART regimen consisting of Emtricitabine [40 mg/kg], Tenofovir Disproxil

614   Fumarate [5.1 mg/kg] and Dolutegravir [2.5 mg/kg]) administered as previously described(31).

615

616   **Specimen Collection and Processing.** Animals were anesthetized with 10mg/kg of ketamine

617   hydrochloride administered intramuscularly for routine collections and with pentobarbital at

618   necropsy. Collection of plasma, serum, and PBMCs were performed as previously described (55).

619   Cerebrospinal fluid (CSF) was collected via the foramen magnum and examined for blood

620   contamination by both visual inspection and Hemastix^{TM} testing strips (Siemens) in accordance

621   with manufacturer instructions. Lymphoid tissues and CNS-associated tissues were obtained at

622   necropsy following cardiac saline perfusion and immediately processed for isolation of

623   mononuclear cells using collagenase IV digestion and a 21/75% Percoll gradient.

624

625   **Flow Cytometry.** Whole blood, CSF, and fine needle lymph node aspirates (FNA) were freshly

626   stained and acquired on the same day following collection. Mononuclear cells obtained from

627   necropsy tissues were either freshly stained and acquired the same day or stained following

628   cryopreservation, with identical methods used for all comparisons. Antibody information can be

629   found in Table S3. Sample acquisition and fluorescence measurements were performed on a BD

630   Bioscience FACSymphony utilizing FACSDiva software (Version: 8.0.1). Sample compensation,

631   population gating, and analysis was performed using FlowJo (Version 10.8.1)

632

633   **Intracellular Cytokine Stimulation Assay.** Aliquots of 2 million freshly collected PBMCs and

634   CSF cells were stimulated with PMA/Ionomycin (eBioscience Cell Stimulation Cocktail) and

635   incubated for 1 hour at 37°C. Brefeldin A (BD GolgiPlug) and monensin (BD GolgiStop) was added

636   to cell suspensions and incubated at 37°C for an additional 4 hours. The remainder of the

637   procedure was carried out as previously described(56).

638

639   **FlowSOM.** Clustering of cells and construction of a minimum spanning tree of relationships

640   between clusters was conducted using FlowSOM, version 2.4.0 (57) with logicle transformation

641   (58). Clustering was based on CXCR3, CD95, PD-1, CD69, CCR5, and, with CCR7 expression

642   used to define groups within metaclusters. Numbers of metaclusters were selected dynamically

643   by the FlowSOM algorithm. Data from each panel was analyzed separately with a cluster defined

644   as overrepresented in the CCR7+ or CCR7- group, if the corresponding adjusted standardized

645   residual from the chi-square test performed on the table of cluster cell counts by CCR7 status

646   was greater than 3. Analyses were conducted using R version 4.2.1.

647

648   **Viral RNA Quantification.** Quantification of plasma and CSF viral RNA (vRNA) was performed

649   as previously described, using a quantitative reverse transcriptase polymerase chain reaction

650   (qRT-PCR) assay for the detection of SIV gag (59).

651

652   **Cell Preparation for Sequencing Studies.** Cryopreserved mononuclear cells from rhesus brain

653   and splenic tissues were thawed at room temperature, placed in fresh complete media (For

654   splenic cells: RPMI supplemented with 10% HI-FBS, 1% L-glutamine, 1% penicillin-streptomycin;

655   For brain tissue derived cells: DMEM supplemented with 10% HI-FBS, 1% L-glutamine, 1%

656   penicillin-streptomycin) and treated with 2 units/mL of DNase I (Roche Diagnostics) for 15 minutes

657   at 37°C. Cells were washed in complete media and CD45+ cells were isolated using CD45

658   microbeads for non-human primates (Miltenyi Biotech) in accordance with the manufacturer's

659   protocol. Enriched CD45+ cells were stained for CD45 and a live dead marker for subsequent

660   flow cytometric sorting. Live CD45+ cells were characterized and quantified on a BD

661   FACSymphony cell analyzer and sorted utilizing a FACS Aria and suspended in DMEM for single

662   cell RNA sequencing studies.

663

664   **Single Cell RNA sequencing.** Sample processing, including barcoding, gel-bead assembly in

665   emulsion (GEM), GEM reverse transcription, cDNA amplification, and library construction,

666   followed the Chromium Next GEM single cell 3' v3.1 protocol by 10X Genomics. Sequencing and

667   bioinformatic analysis was performed as previously described (31). Differential gene expression

668   (DGE) analysis across different cell types and conditions was conducted using Seurat functions,

669   employing a threshold of (adjusted P-value < 0.05, |log2 FC| > 0.25) with Benjamini-Hochberg

670   correction. Gene-set enrichment analysis and functional annotation were carried out using

671   clusterProfiler 4.0 and visualized through custom scripts. Pathways represented by DGE genes

672   were visualized with a chord plot utilizing the 'circlize' package in R. All subsequent data analysis

673   was performed in R v4.2.0.

674

675   **Single nuclei RNA-seq and ATAC.** Nuclei were isolated from brain derived live CD45+ and

676   CD45- cells using the Chromium Nuclei Isolation Kit (10X Genomics) using manufacture

677   instructions. Following isolation, nuclei were stored on ice and used immediately for subsequent

678   library preparation. Barcoded 3' single cell gene expression library and ATAC library were

679   prepared from single nuclei suspensions using the Chromium Single Cell Multiome kit (10X

680   Genomics) following the manufacturer's instruction. The libraries were quantified by fluorometry

681   on a Qubit instrument (LifeTechnologies) and by qPCR with a Kapa Library Quant kit (Kapa

682   Biosystems-Roche) prior to sequencing. The libraries were sequenced on a NovaSeq 6000

683   sequencer (Illumina) with paired-end 150 bp reads with approximately 35,000 reads pairs per

684   nuclei for gene expression and 25,000 read pairs per nuclei for ATAC libraries.

685

686   **Single nuclei RNA-seq and ATAC quantification and statistical analysis**. The raw single-cell

687   multiome (ATAC + Gene Expression) sequencing data was pre-processed using Cell Ranger

688   ARC pipeline (10X Genomics). This step involves the demultiplex of cells using cell barcodes, the

689   alignment of reads to Mmul10 reference genome, removal of empty droplets, cell debris and low-

690   quality cells. The filtered gene expression data was imported to Seurat (60) (v4.3.0) for further

691   quality control. Cells were required to have between 250 and 5000 genes, 500 and 12000 unique

692   transcripts, and 1000 and 70000 ATAC peaks. Cell doublets were removed using DoubletFinder

693   (61). Gene expression data and chromatin accessibility data were normalized, and dimensionality

694   reduced individually using LogNormalize method in Seurat with a scale factor of 10000. Chromatin

695   accessible peak data produced by Cell Ranger was processed using Signac (62) (v1.8.0) and

696   normalized using term frequency-inverse document frequency (TF-IDF) in RunTFIDF function,

697   selecting the top features and then dimension reduced using singular value decomposition on the

698   TF-IDF matrix. After dimension reduction, the two modalities were integrated using the weighted

699   nearest neighbor method in Seurat. The integrated graph was then used for UMAP visualization

700   and clustering. Cell type identification was carried out on clusters generated at resolution 2.25,

701   using the R package scType (63). Differential expression analysis was done using a linear model

702   in limma (64), adjusting for cell cycle scores and the number of genes expressed.

703

704   **Spatial Transcriptomics Profiling.** Paraformaldehyde-fixed, paraffin-embedded hippocampal

705   brain tissues were profiled using GeoMx® DSP (65). 5 μm tissue sections were prepared

706   according *f*to manufacturer's recommendations for GeoMx-NGS RNA BOND RX slide

707   preparation (manual no. MAN-10131-02). Tissue morphology was visualized using fluorescent

708   antibodies specific to lymphocyte and neuron specific markers (anti-CD45 [Novus], anti-CD3

709   [Primary, Bio-Rad], Secondary anti-Rat IgG, [ThermoFisher], and anti-NeuN [Millipore Sigma],

710   and nucleic acid stain Cyto83 [ThermoFisher]). Twelve regions of interest (ROIs) of 660 x 785 μm

711   geometric shapes (squares) were created and localized to brain blood vessels and neuron rich

712   areas. After ROI selection, UV light was utilized to release and collect oligonucleotides from each

713   ROI. For Whole Transcriptome analysis, Illumina i5 and i7 dual-indexing primers were added to

714   each area of illumination (AOI) during PCR. Library concentration was measured using a Qubit

715   fluorometer (Thermo Fisher Scientific), and quality assessed using a Bioanalyzer (Agilent). The

716   Illumina NextSeq 2000 was used for sequencing, and the resulting FASTQ files were mapped to

717   the Hs_R_NGS_WTA_v1.0 reference (Nanostring) using the NanoString GeoMx NGS pipeline

718   v2.1 to generate raw count data/ each target probe AOIs. Raw counts were processed using the

719   same NanoString GeoMx NGS pipeline and converted to digital count conversion (DCC) files. For

720   protein analysis, oligos were enumerated on the nCounter platform. Protein data was normalized

721   to ERCC-sequence specific probes followed by area normalization, and lastly to control IgG

722   (rabbit and mouse) to control for background signal.

723

724   DCC files were further processed using Geomxtools (66) R package (Bioconductor version 3.2.0,

725   Nanostring, Seattle, WA, USA). Data were quality controlled per individual AOI. AOIs were

726   excluded from the dataset if they met any of the following conditions: less than 80% reads aligned

727   to the reference, less than 40% sequencing saturation, or less than 1000 raw reads. Limit of

728   quantification (LoQ) calculated for raw data based on the distribution of the negative control

729   probes ("NegProbe") and used as an estimate for the quantifiable limit of gene expression per

730   AOI (67). A gene was considered detected if its expression is above the LoQ for that AOI. Genes

731   were included in the analysis if they were detected above the LoQ in > 5% of AOIs. Then, the

732   data was normalized using the third quantile (Q3) to account for differences in cellularity and ROI

733   size. The Linear Mixed Model (LMM) was used to calculate the significant differences between

734   the two groups, and genes were considered significantly expressed when adj.p < 0.1 (677 DGEs).

735   The differentially expressed genes were used to create heatmaps of selected KEGG pathways.

736   The heatmaps were created using ComplexHeatmap (version 2.13.1) R package (68).

737

738   **Immunohistochemistry.** De-identified formalin-fixed paraffin embedded human hippocampal

739   tissues from non-demented patients (n=3) and a patient with glioblastoma (n=1) were obtained

740   from the Netherlands Brain Bank and human tonsil tissues (n=1) was obtained from the UC Davis

741   Cancer Center Repository. Rabbit polyclonal anti-CD3 (Agilent), mouse monoclonal anti-CD4

742 (Novus), rabbit polyclonal anti-CD45 (Novus), rabbit monoclonal anti-IBA1 (Invitrogen), rabbit

743 polyclonal anti-CD11b (Invitrogen), and rabbit monoclonal anti-NeuN (Abcam) were used for

744 subsequent immunohistochemical staining. All 4 μm paraffin sections were subjected to a heat

745 antigen retrieval step before application of primary antibodies by treating slides with AR-10

746 (Biogenex) for 2 minutes at 125°C in a Digital Decloaking Chamber (Biocare), followed by cooling

747 to 90°C for 10 minutes, or by treating slides with H-3300 (Vector) for 20 minutes at

748 100°C. Following primary staining, samples were incubated with anti-mouse and anti-rabbit

749 EnVision+ system secondary antibodies (Agilent), followed by treatment with AEC chromogen

750 (Agilent) and counterstained with Gill's hematoxylin I (StatLab). Primary antibodies were replaced

751 by mouse or rabbit isotype controls and ran with each staining series as negative controls. Slides

752 were visualized with a Zeiss Imager Z1 (Carl Zeiss) and images captured using a Zeiss Axiocam

753 (Carl Zeiss).

754

755 **Statistical Analyses.** Wilcoxon signed rank test were used for paired analyses (i.e., longitudinal

756 and within group comparisons). Mann-Whitney U-test were used for unpaired comparison

757 between animal cohorts/treatment groups. Tests were performed in GraphPad Prism (Version

758 9.5.1) with significance values denoted as follows: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$, **** $p < 0.0001$.

759 0.0001.

760

761 **Study Approval.** All nonhuman primates were maintained according to the guidelines of the

762 IACUC of University of California, Davis, based on the approved protocol (#22379, 22261, 22787,

763 22033, 23363)

764

765 **Data and materials availability.** RNA-seq dataset is accessible at GSE221815. All data are

766 provided in the Supporting data values file.

Figure 1. **Single-cell transcriptomic analysis of CD45+ leukocytes identifies core T cell gene signatures in the rhesus brain. (A-C)** Schematic of single CD45+ cell profiling in brain, right hemisphere (RH) and spleen. **(D)** Differences in B and T cell transcripts in brain versus spleen. **(E)** UMAP of scRNA-seq transcriptional profiles from brain and spleen identifies 10 clusters. Cell clusters are color-coded based on cell identity assigned using Single R. SkM, skeletal muscle; MBC, memory B cells; Mono, monocytes. Inset shows cell proportions in each cluster split by tissue type (bottom, spleen; top, brain). **(F)** UMAP shows 10 sub-clusters from T cell clusters in E.
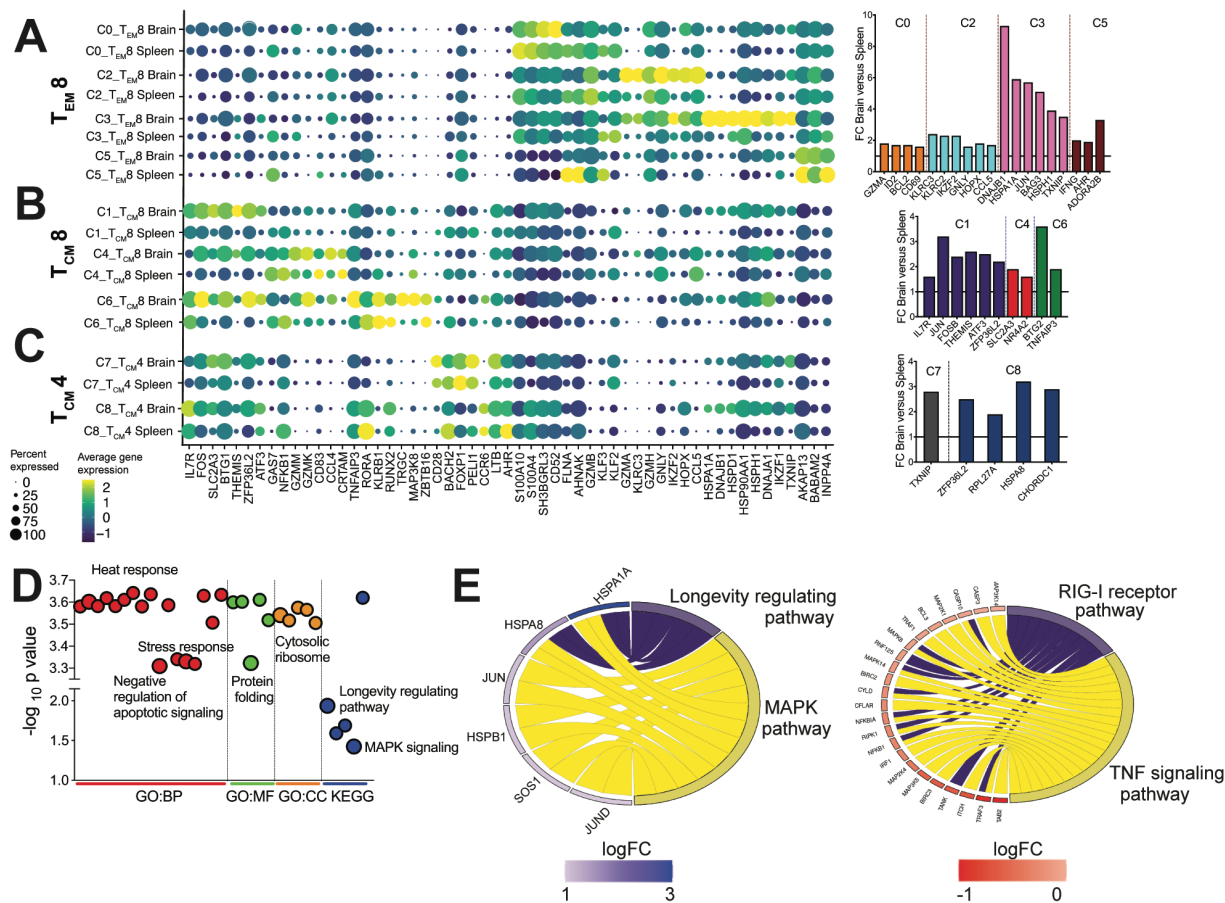

Figure 2. T cell clusters in rhesus brain. (A-C) Select marker genes of cell clusters. Dot size represents proportion of cells expressing gene and color designates expression level with bar graphs representing genes significantly higher in brain relative to spleen for indicated clusters. **(D)** Dot plot displays link between genes and pathways from GO biological processes (GO:BO), GO molecular functions (GO:MF), and GO cellular component (GO:CC) and KEGG. **(E)** Chord plots show pathways and corresponding genes enriched versus underrepresented in $T_{CM}4$ cell clusters.
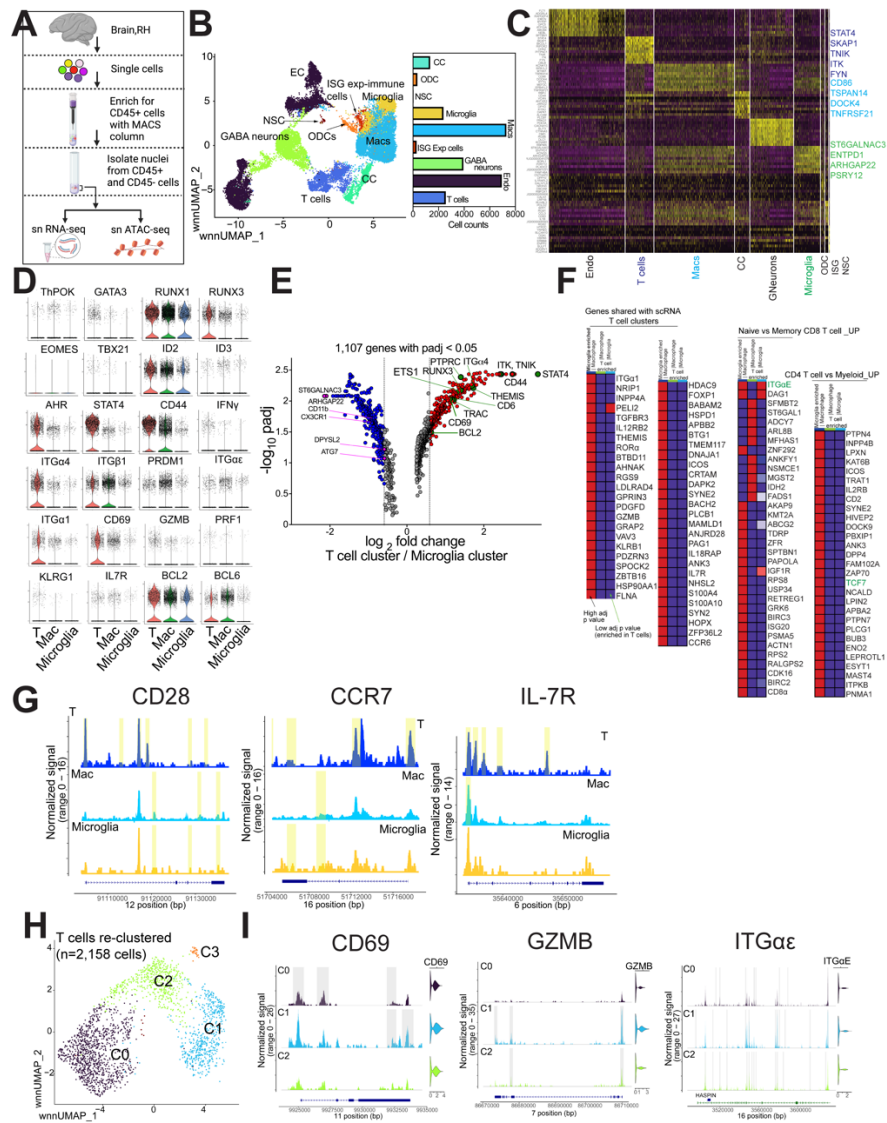

Figure 3. T$_{CM}$/T$_{RM}$ loci accessible in T cells within the brain. (A) Schematic of sn RNA analysis. (**B**) UMAP projection of 25,321 snRNA-seq profiles. Dots represent individual cells, and colors indicate cluster identity (labelled on right). EC, endothelial cells; NSC, neural stem cells; CC, cancer cells; Macs, macrophages; ODC, oligodendrocyte precursor cells; ISG exp cells, interferon stimulated gene expressing cells. (**C**) Heat map representation of RNA-seq of cluster-specific marker genes across all clusters. (**D**) Violin plots show expression of key genes across immune clusters. (**E**) Gene expression differences between T cell and microglial cell clusters. (**F**) GSEA of shared genes across sn and sc analysis**. (G)** Genomic regions showing snATAC-seq tracks of chromatin accessibility of T$_{CM}$ genes across T cell, microglia, and macrophage immune clusters. (**H**) UMAP projection of 3 major T cell subclusters (2,158 T cells). (**I**) Genomic regions showing snATAC-seq tracks of chromatin accessibility of T$_{RM/EM}$ genes across 3 major T cell clusters (C0-C2) in H.
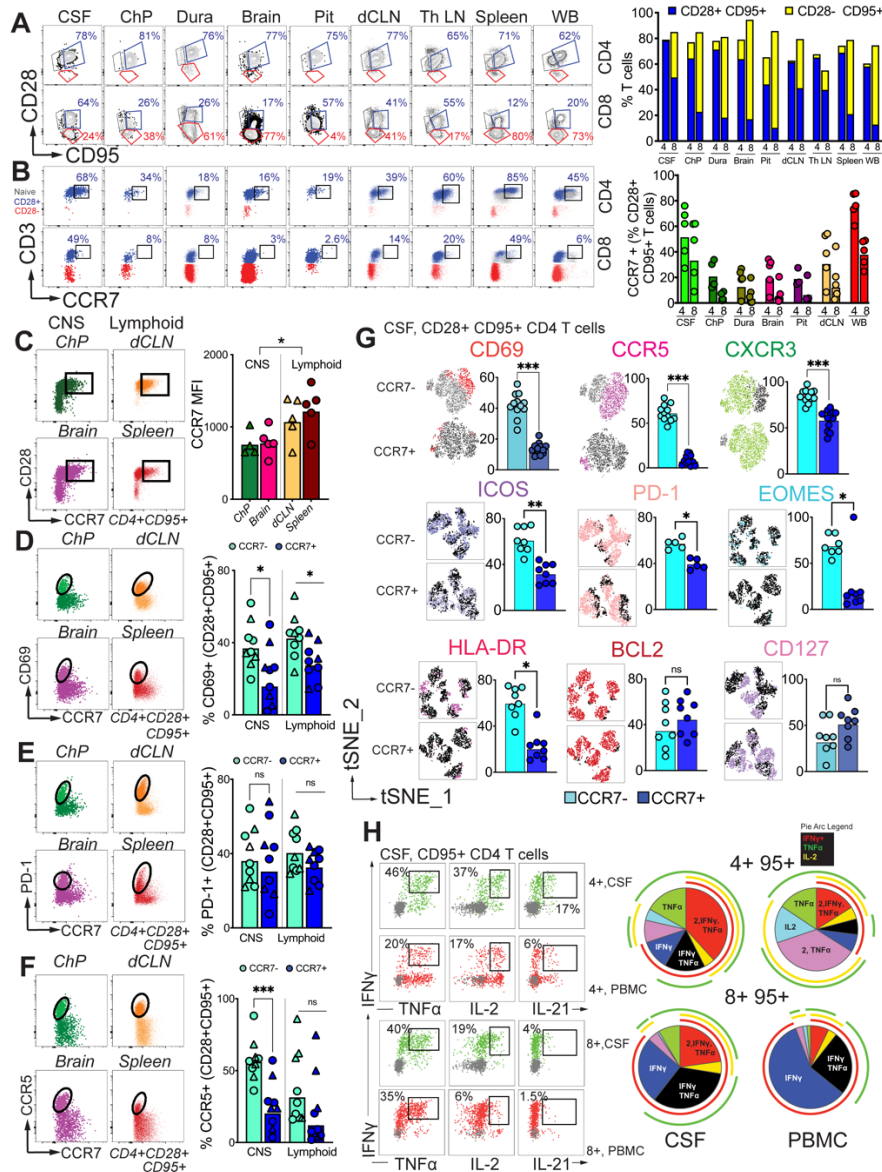

Figure 4. CCR7⁺ CD4 T cells in CNS share phenotypic features with T_CM in blood and lymph nodes. (A) Representative flow plots illustrate CD28 and CD95 expression on CD4 and CD8 T cells; frequencies of CD28+CD95+ (blue) and CD28-CD95+ (yellow) in CD4 T cells and CD8 T cells. **(B)** Representative flow plots illustrate CCR7 expression on CD28^High CD4 (top row) and CD28^High CD8 (bottom row) T cells; frequencies of CCR7 expression on CD28^High CD4 and CD28^High CD8 T cells. **(C)** Representative flow plots illustrate CD28 expression and CCR7 expression on CD4+CD95+ T cells in CNS and lymphoid tissues; CCR7 MFI of CD4+CD95+. **(D-F)** Representative flow plots indicating CD69, PD-1, CCR5 and CCR7 expression on CD4+CD28+CD95+ T cells in CNS and lymphoid tissues; frequency of CD69+, PD-1+, and CCR5+ on CD4+CD28+CD95+ CCR7-/+ T cells. **(G)** Representative tSNE plot illustrating expression of T cell markers on CD4+CD28+CD95+ CCR7-/+ T cells in the CSF; frequencies for each population. **(H)** Representative flow plots illustrating cytokine production in the CSF and PBMCs. CSF, cerebrospinal fluid; ChP, choroid plexus; Pit, pituitary; dCLN, deep cervical lymph nodes; Th LN, thoracic lymph node. Parenchyma refers to brain parenchyma.
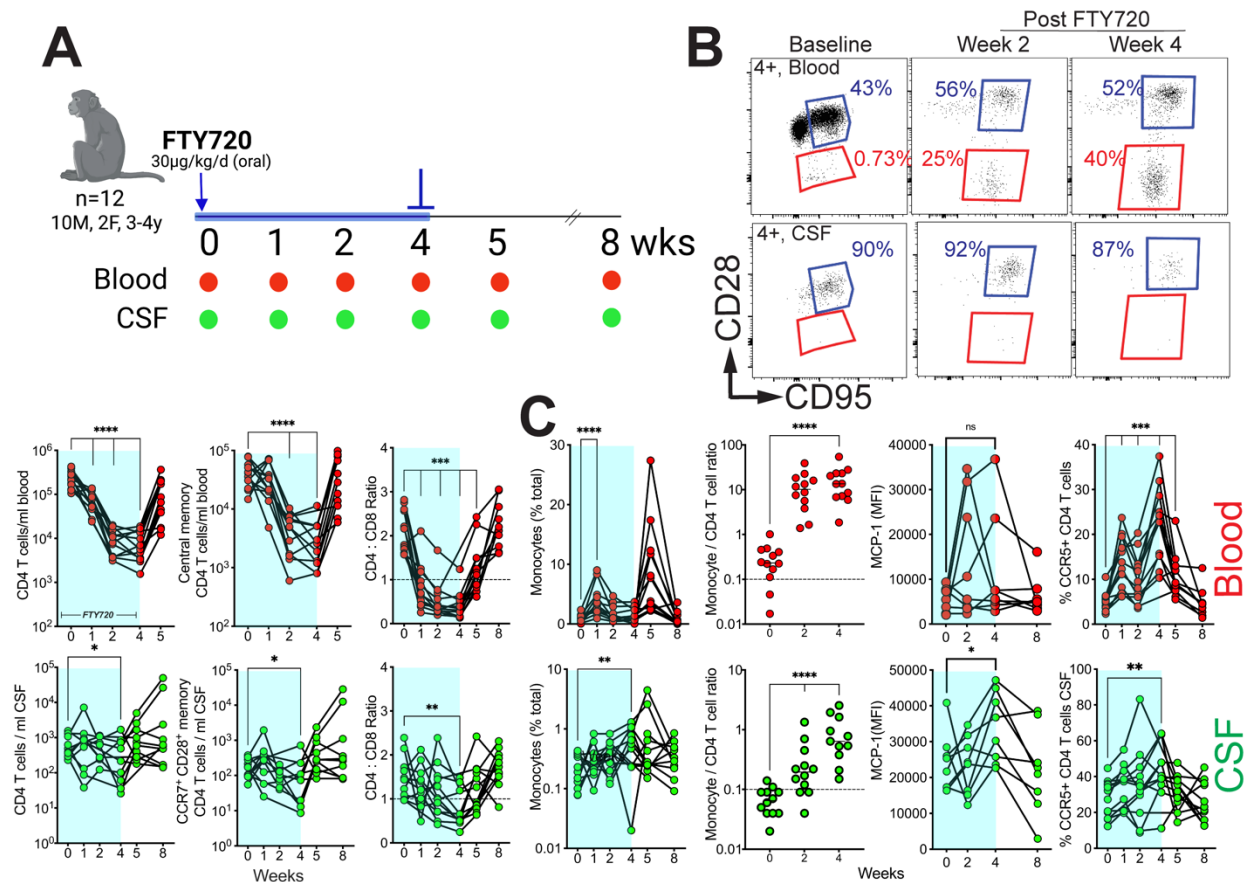

Figure 5. Sequestration of CD4 T_{CM} in lymphoid tissues reduces CCR7$^+$ CD4 T cell frequencies in CSF. (A) Study schematic: n= 12 rhesus macaques (age,3-4 years) were administered an oral dose of 30 µg/kg per day of FTY720 for the first four weeks of the study. CSF taps and blood draws were performed at indicated timepoints. **(B)** Representative flow plots indicating CD28 and CD95 expression on CD4 T cells from the blood (top row) or the CSF (bottom row) (Left); CD4 T cell counts/ml, Central memory CD4 T cells and CCR7+CD28+ memory CD4 T cells/ ml blood or CSF, and CD4:CD8 Ratio for Blood and CSF (Right). **(C)** Frequencies of Monocytes, Monocyte to CD4 T cell ratio, Median Fluorescent Intensity (MFI) of Monocyte Chemoattractant Protein-1 (MCP-1), and CCR5 expression of CD4 T cells in the blood and CSF over the course of the study.
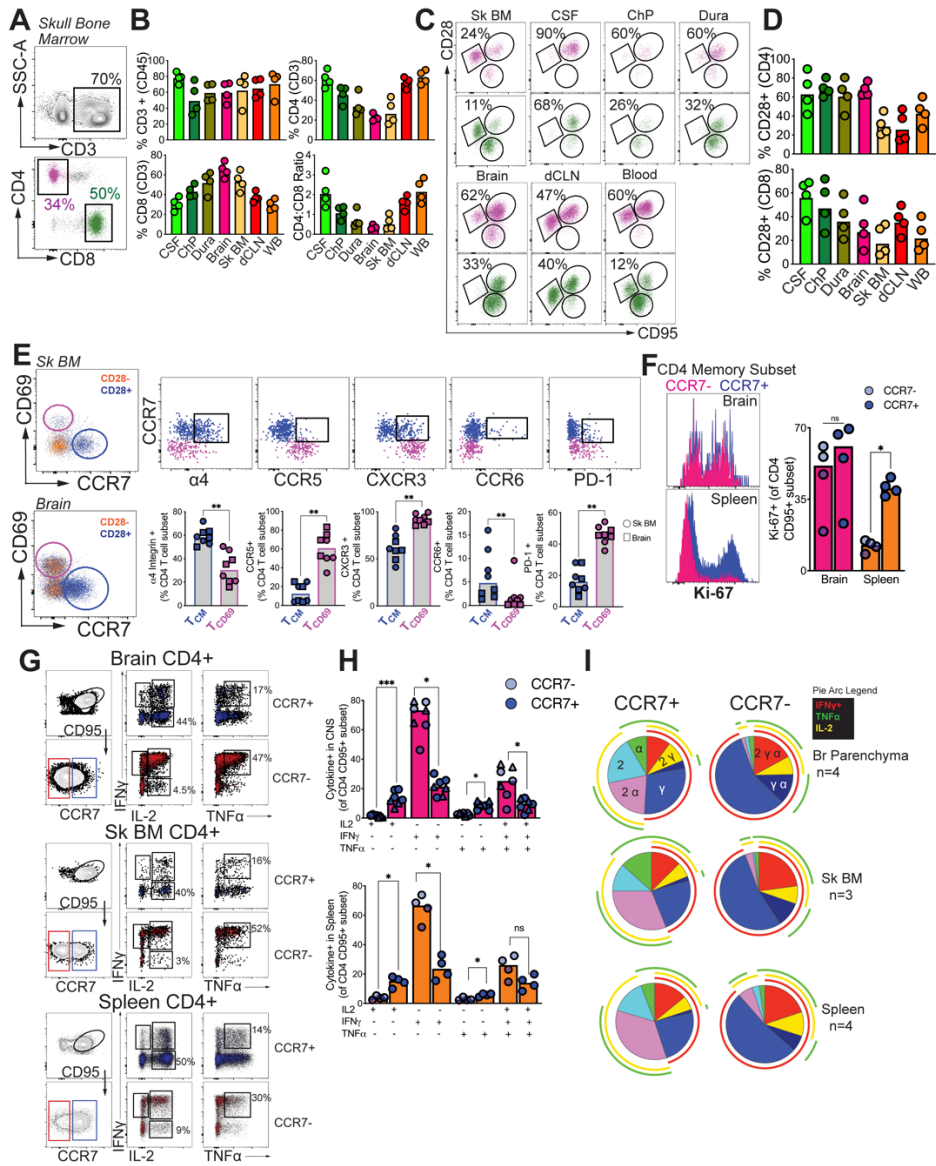

Figure 6. CCR7+ CD4 T cells in CNS exhibit functional T_CM features and reside within skull bone marrow. (A) Representative gating for T cells within the skull BM and **(B)** corresponding frequencies of CD3, CD4 (top), CD8 T cells, and CD4/CD8 ratios (bottom) across tissue compartments. **(C)** Population gates for CD4 (purple) and CD8 (green) subsets with **(D)** corresponding frequencies of CD28+ subsets across tissue compartments. **(E)** Phenotypic characterization of T_CM-like (CCR7+; blue) and tissue resident (CD69+; purple) CD4 T-cells from brain and skull BM. **(F)** Ki67 MFI and frequencies on CCR7- and CCR7+ CD4 T cells after T cell activation using anti-CD3 and anti-CD28. **(G-I)** Representative gating for CD95+ CCR7+ CD4 T cells and CD95+ CCR7- CD4 T cells and bar charts illustrating cytokine production after stimulating with PMA/Ionomyocin in Brain, Skull BM, and Spleen. **(I)** Pie Charts indicating cytokine functionality after PMA/Ionomycin treatment. **(A-F)** Data points indicate individual tissue samples. **(F)** Symbols indicate skull BM (circle) or brain tissue (square) samples. Bars indicate medians.
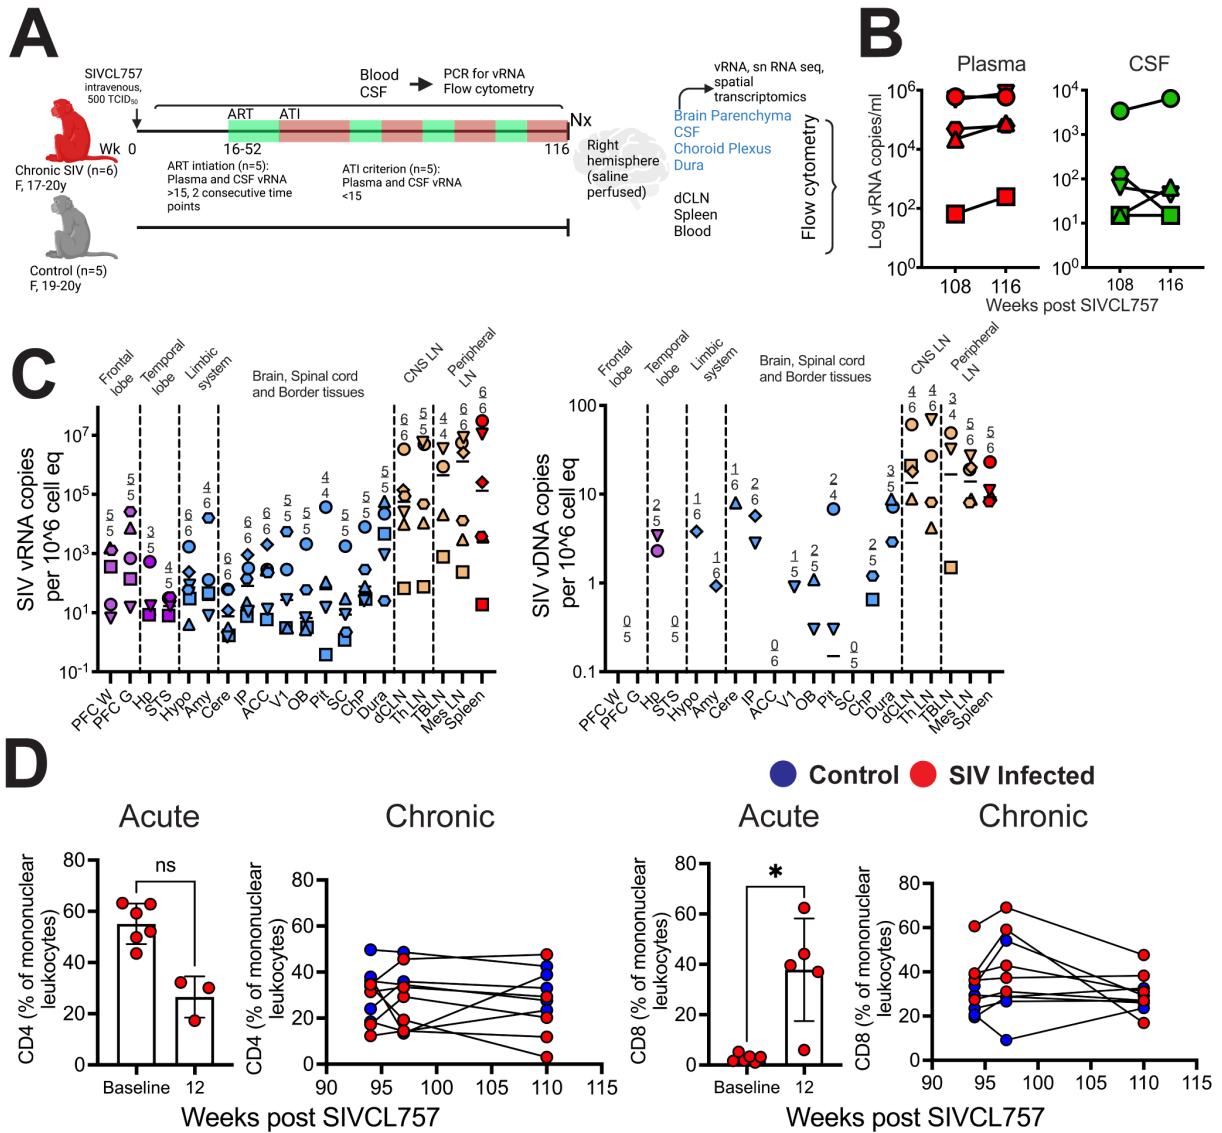

Figure 7. vRNA within frontal and temporal lobes during chronic SIV infection. (A) Study schematic: rhesus macaques were infected with SIVCL757 intravenously and longitudinally assessed for systemic and CNS viral burden, single nuclei (sn) RNA sequencing, spatial transcriptomics and immune responses by flow cytometry. **(B)** Kinetics of plasma (red) and CSF (green) viral loads during the chronic phase (wk108 – 116) of SIVCL757. **(C)** vRNA and vDNA in various brain regions, dura mater, deep cervical lymph nodes, and PBMCs. **(D)** CSF CD4 and CD8 frequencies during the acute phase (week 12) and chronic phase (week 92-110) of SIVCL757 infection. PFC W, pre-frontal cortex white matter; PFC G, PFC gray matter; Hp; hippocampus; STS, superior temporal sulcus; Hypo, Hypothalamus; Amy, Amygdala; Cere, Cerebellum; IP, inferior/intra parietal; ACC, anterior cingulate cortex; V1, primary visual cortex; OB, olfactory bulb; Pit, pituitary; SC, spinal cord (near base of skull); ChP, choroid plexus; dCLN, deep cervical lymph node; Th LN, thoracic lymph node; TBLN, tracheobronchial lymph nodes; Mes LN, mesenteric lymph nodes.
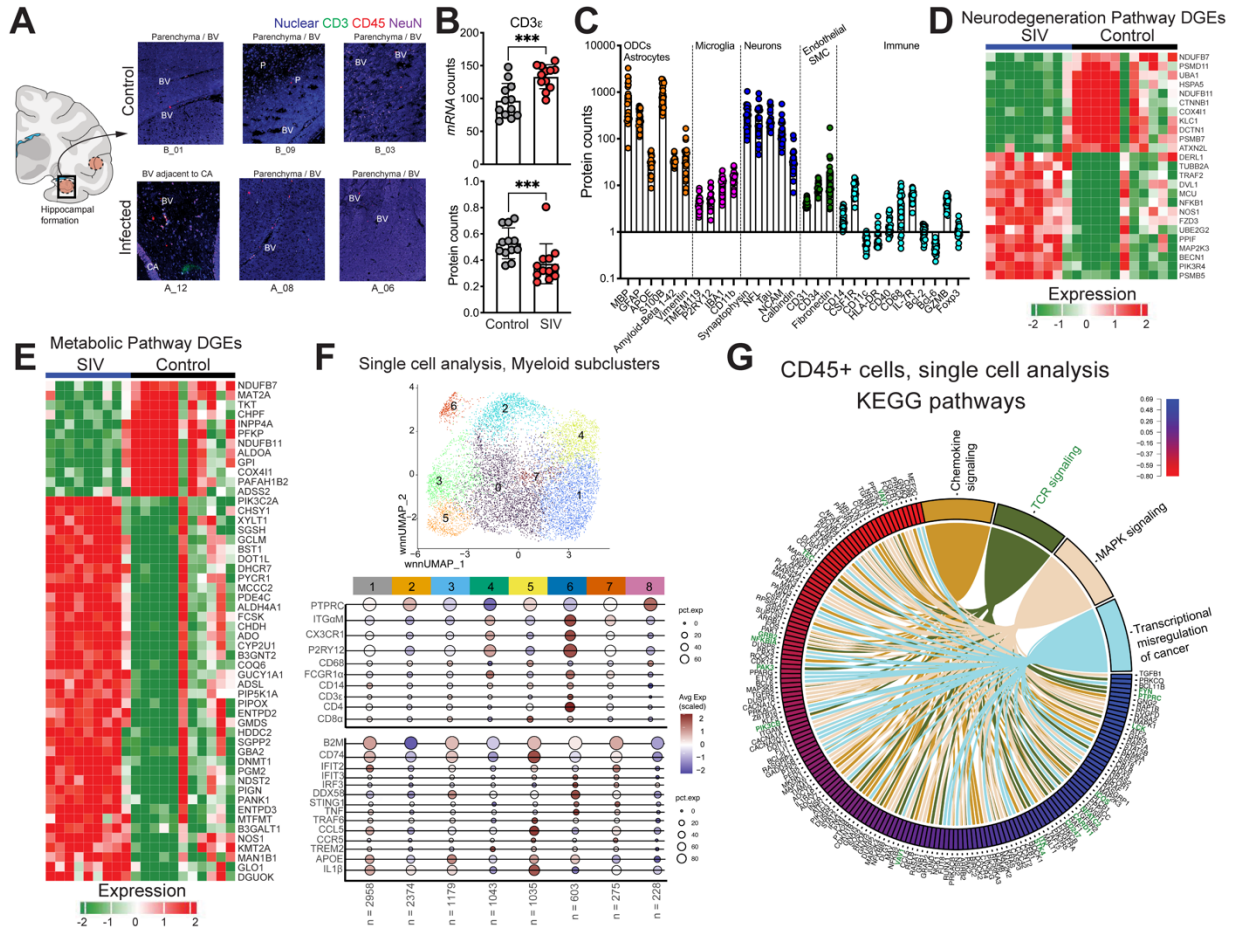

Figure 8. Induction of neuroinflammatory and neurodegenerative gene programs during chronic SIV infection. (A) Representative illustration for ROI selection within the hippocampal region of control (top) and SIVCL757 infected (bottom) animals; Nuclear (blue), CD3 (green), CD45 (red), and NeuN (Purple) for Nanostring whole transcriptome analysis (WTA) and proteomics pipeline. **(B)** CD3ε *mRNA* and protein counts for ROIs. **(C)** Protein counts for all ROIs. **(D)** Differentially expressed neurodegenerative genes across control and SIV infected ROIs. **(E)** Differentially expressed metabolic genes across control and SIV infected ROIs. **(F)** UMAP plot shows cell annotation for myeloid specific gene clusters from sc data. Dot plots depict average gene expression of canonical microglia, monocyte, macrophage, antiviral and inflammatory response genes across 8 distinct myeloid clusters. **(G)** Chord plot of differentially expressed genes across control and SIV infected CD45-enriched cells from single cell transcriptomics. Genes related to TCR signaling pathway are colored in green for clarity.
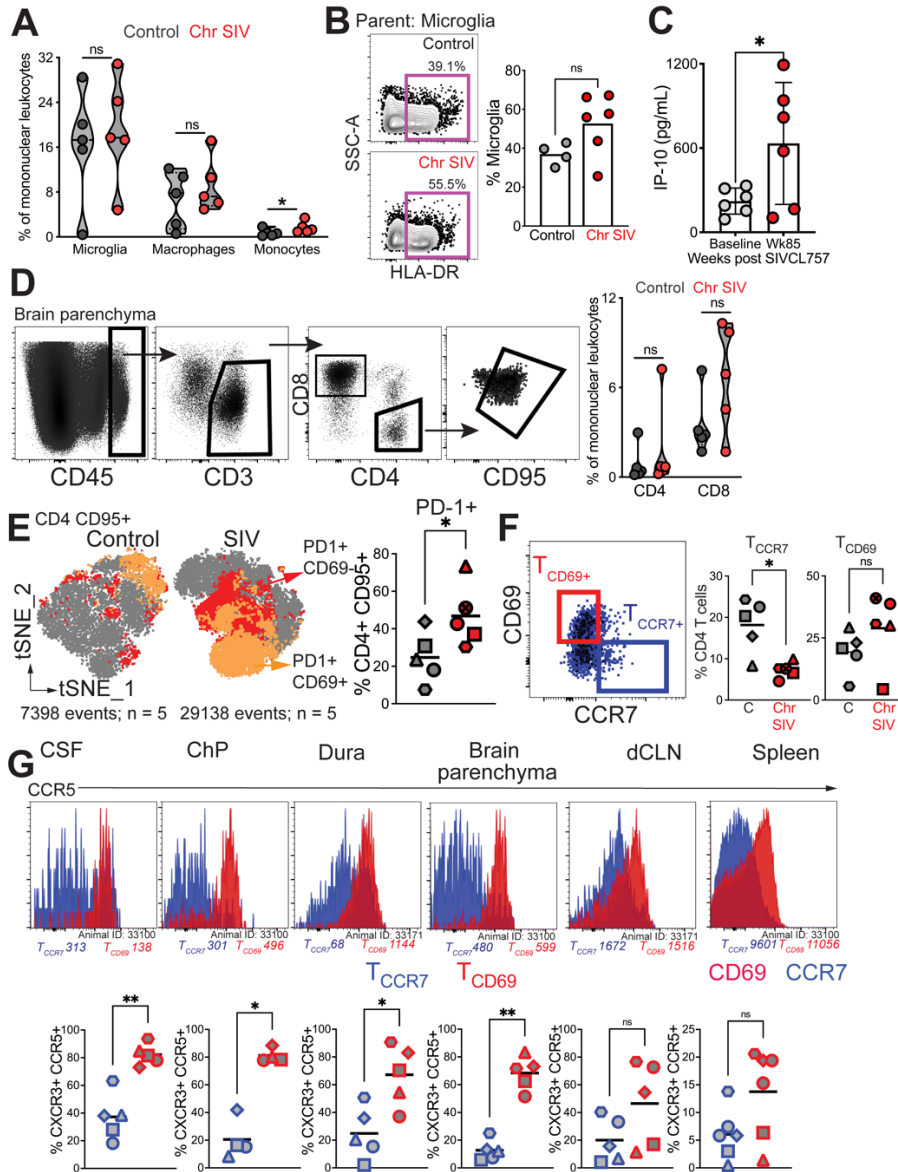

Figure 9. CCR7+ CD4 T cell frequencies decreased during SIV-induced neuroinflammation. **(A)** Frequencies of Myeloid (microglia, macrophage, and monocytes) within the control (black) and chronically infected SIV brain (red). **(B)** Representative flow plot illustrating HLA-DR expression on microglia cells (left); Frequency of HLA-DR expression (right). **(C)** IP-10 concentration within the rhesus CSF between baseline (grey) and chronic SIV CL757 infection (red; week 85). **(D)** Representative flow plots show CD4 and CD8 T cells in brain (left) and scatter plot shows frequencies (right). (**E**) t-SNE plot shows distribution of PD-1+ cells control and SIV brain (left) and scatter plot shows significantly higher PD-1+ frequencies with chronic SIV (right). **(F)** Representative flow plots depict gating strategy for T_{CD69+}(red gate) and T_{CCR7+} (blue gate) populations (left); Frequencies of T_{CCR7} and T_{CD69} populations (right) in the control (grey) and chronic SIV CL757 (red) infected brain. (**G**) Histogram plots indicating CCR5 expression and MFI (top) on T_{CCR7} (blue) and T_{CD69} (red); Frequencies of CXCR3+CCR5+ within T_{CCR7} and T_{CD69} across the CSF, Choroid plexus (ChP), Dura, Brain Parenchyma, deep cervical lymph node (dCLN) and spleen.
